HANDLING DIFFERENT TYPES OF TELECOMMUNICATION SIGNALS

APPLICANT(S) FOR DO/EO/US

Haim GUATA

Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information

1. ☒ This is a **FIRST** submission of items concerning a filing under 35 U.S.C. 371
2. ☐ This is a **SECOND** or **SUBSEQUENT** submission of items concerning a filing under 35 U.S.C. 371
3. ☒ This is an express request to begin national examination procedures (35 U.S.C. 371(f)) at any time rather than delay examination until the expiration of the applicable time limit set in 35 U.S.C. 371(b) and PCT Articles 22 and 39(1)
4. ☒ The US has been elected in a Demand by the expiration of 19 months from the priority date (PCT Article 31)
5. ☒ A copy of the International Application as filed (35 U.S.C. 371(c)(2))
 - a. ☐ is attached hereto (required only if not transmitted by the International Bureau)
 - b. ☒ has been communicated by the International Bureau
 - c. ☐ is not required, as the application was filed in the United States Receiving Office (RO/US)
6. ☐ An English language translation of the International Application as filed (35 U.S.C. 371(c)(2))
7. ☒ Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371(c)(3))
 - a. ☐ are transmitted herewith (required only if not transmitted by the International Bureau).
 - b. ☐ have been communicated by the International Bureau
 - c. ☐ have not been made, however, the time limit for making such amendments has NOT expired.
 - d. ☒ have not been made and will not be made
8. ☐ An English language translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371(c)(3)).
9. ☒ An oath or declaration of the inventor(s) (35 U.S.C. 371(c)(4))
10. ☐ An English language translation of the annexes to the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371(c)(5)).

Items 11. to 16. below concern document(s) or information included:

11. ☒ An Information Disclosure Statement under 37 CFR 1.97 and 1.98
 12. ☐ An Assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included
 13. ☒ A FIRST preliminary amendment.
 - ☐ A SECOND or SUBSEQUENT preliminary amendment
 14. ☐ A substitute specification
 15. ☐ A change of power of attorney and/or address letter.

HANDLING DIFFERENT TYPES OF TELECOMMUNICATION SIGNALS

FIELD OF THE INVENTION

5 The present invention relates to telecommunication systems in general, and in particular to the transmission of various types of signals in telecommunication systems.

BACKGROUND OF THE INVENTION

10

Different sorts of signals may be transmitted through telecommunication systems. Among these signals are voice signals, facsimile signals, data signals, video signals etc. Furthermore, in today networks, signals may
15 also be classified by their quality, a characteristic that is used to differentiate between different quality of services.

Various types of telecommunication systems are known in the art and in the marketplace for interconnecting
20 telephone communication trunks to transmission network. One type of such systems is known as Digital Circuit Multiplication Equipment (to be referred to hereinafter as "DCME") systems.

In order to use network available resources as
25 efficient as possible, many solutions were suggested in the past. One such example is the use of optimal ADPCM algorithm in DCME systems, where this algorithm is adapted for transmission of compressed voiceband data. This solution allows achieving a typical compression rate
30 of 2:1. However, when taking into account that the compression rate of the DSI and the ADPCM algorithms for speech is 6:1, it is understood why even such an improved algorithm presents a bottleneck in these systems. In the recent years, the use of facsimile machines is constantly

531 Rec'd PCT/ 31 DEC 2001

growing, and since facsimile signals are transmitted via DCME systems when compressed as voiceband data, the overall compression rate that can be achieved for DCME systems approaches 3:1 ratio. When using more advanced encoding algorithms such as LD-CELP and CS-ACELP, higher compression rates may be achieved, as the typical overall compression rates are 8:1 and 16:1, respectively. Nevertheless, in view of the developing traffic load in telecommunication systems, there is a constant strive for better utilization of the network resources available which in turn will allow to reduce communication costs while maintaining required qualities of service.

Therefore, it is understandable why solutions for better utilization of resources both in TDM and non-TDM systems, such as IP systems, are to be found.

SUMMARY OF THE INVENTION

It is therefore an object of the present invention to provide a novel digital telecommunication station capable of transmitting various signals.

It is another object of the present invention to provide a digital communications system utilizing efficiently the resources available for communication transmissions by diverting less urgent signals based on their type, to another transmission path, thereby increasing the bandwidth available at the main transmission path for the transmission of more urgent signals.

Yet another object of the present invention is to provide a method for handling different types of communication traffic.

Further objects and features of the invention will become apparent to those skilled in the art, from the following description and the accompanying drawings.

In accordance with a first embodiment of the present invention there is provided a digital telecommunication

station operative in a telecommunication network and comprising:

at least one detector operative to receive at least two different types of signals and determine their type;

5 at least one switch controlled by one of said at least one detector, operative to channel signals received in accordance with the determination made by said one of the at least one detector;

10 a first transmission means operative to transmit the received signals along a first transmission path, wherein signals of at least one type may be diverted from the first transmission path along which signals of the other types are transmitted; and

15 a second transmission means operative to transmit the diverted signals of the at least one type along a second transmission path.

The term "telecommunication network", as will be used hereinafter, should be understood to encompass the various types of networks known in the art, such as TDM, synchronous and asynchronous transfer networks, IP networks, IP frame relaying networks and any other applicable communication networks.

25 The term "different types of signals" as used herein, should be understood to encompass both signals belonging to different groups of signals e.g. voice signals, facsimile signals, data signals, voiceband data signals and video signals, as well as signals of the same group having different quality, e.g. voice signals that are adapted to different Quality of Service ("QoS").

30 In accordance with the present invention, the telecommunication station is provided with a detector to determine the type of the signals received and a switch to channel these signals in accordance with their type. However, in some cases, the use of such a detector and a switch may be
35 avoided when the transmission of signals of certain type(s), is received with a priori knowledge of

their type. For example, when a pre-defined trunk is assigned only for delivering a specific type of signals, the fact that a call arrives via this trunk is enough for automatic recognition of the signals' type, and the following handling is carried out accordingly. The present invention should be understood also to encompass this mode of operation.

The process of diverting the signals may be considered as belonging to one of two main types of diversions that are encompassed by the present invention. The first type of diversion is achieved by delaying the diverted signals (e.g. by storing them in a buffer memory) and forwarding them along the first transmission path towards the receiving end at a later stage. The other type of diversion is carried out by transmitting the diverted signals along a different (second) transmission path, with or without delaying their transmission along that second transmission path.

One of the major advantages offered by the present invention is the enhancement of the network real time traffic performance as well as its capacity. Diverting part of the traffic carried along a bearer (the first transmission path), results in increasing bandwidth availability for e.g. transmitting additional voice calls, and consequently in the increase of the overall system performance.

According to yet another preferred embodiment of the invention, the second transmission path to which some of

the signals are diverted, is a path defined in a packetized network such as an IP network and the like.

By yet another embodiment of the invention, the diversion of some of the signals is carried out in accordance with the quality of service required. For example, voice signals for which high quality of service is required will be transmitted along the first transmission path whereas signals, for which lower quality of service is required, are diverted to a second transmission path.

According to a preferred embodiment of the invention, the at least one detector of the digital telecommunication station is capable of detecting facsimile signals and classifying the signals received as selected facsimile signals that are distinguished from other signals. The selected facsimile signals may then be diverted (preferably in accordance with the bandwidth availability) from the first transmission path.

By another preferred embodiment of the invention, the digital telecommunication station further comprises means for encoding/decoding signals received, e.g. demodulating/re-modulating facsimile signals when such signals are received, allowing their transmission in their coded form, preferably along a second transmission path.

As would be appreciated by a person skilled in the art, demodulation and re-modulation may either be complete including, for example, de-scrambling and scrambling, or incomplete, not including scrambling and de-scrambling.

In accordance with yet another preferred embodiment of the invention the demodulating/re-modulating means comprises a plurality of facsimile demodulators, apparatus for initially supplying incoming selected

second identifier for determining whether the transmission path along which the signals will be

transmitted includes at least one further operative means adapted for decompressing the signals when being transmitted in their compressed form;

third transmission means operative in response to a determination made by the second identifier that the transmission path does not include at least one further operative means adapted for decompressing the signals being transmitted in their compressed form; and

fourth transmission means operative in response to a determination made by the second identifier that the transmission path does include at least one further operative means adapted for decompressing the signals being transmitted in their compressed form into the decompressed digital output signals.'

The digital telecommunication station described above, allows operation in a mode where signals that are received by the station already in their coded form are not decompressed when at least one further de-compressor, capable of decompressing these signals transmitted in their compressed form, is operative along the transmission path. Naturally there may be cases where the first transmission path further comprises operative means that are capable of decompressing the compressed signals, whereas the second transmission path does not comprise such further means, or vice a versa. In these cases, the coded signals that should be transmitted along a transmission path that has no such further decompressing means, will be decompressed to their non-compressed form by the station's decompressing device prior to their transmittal.

In accordance with yet another aspect of the invention, there is provided a telecommunication system comprising at least one transmission apparatus at at least a first end of the transmission network and at

least one receiving apparatus at at least a second end of the transmission network. The telecommunication system further comprises at least one digital telecommunication station of the type described above.

5 In accordance with still another preferred embodiment of the invention, a pair of telecommunication stations in the communication system is selectively operated.

By a further embodiment of the present invention at least one of the digital telecommunication stations in the digital
10 communication system is further provided with an option of establishing a communication connection with more than two other digital telecommunication stations. Preferably, such a station is adapted to establish a communication with a plurality of digital telecommunication stations each located
15 at a different part of a telecommunication network. By another embodiment of the present invention, all or part of the transmissions transmitted by a digital telecommunication station, is received in parallel by at least two other digital telecommunication stations.

20 According to another aspect of the present invention there is provided a method for transmission of telecommunication signals of at least two different types, the method comprising:

A method for transmission of telecommunication signals of at
25 least two different types, the method comprising:

- i) determining the type of the signals received and distinguishing therefrom signals of at least one pre-defined type from signals of other types;
- ii) based on step i), diverting signals of a per-defined
30 type from a first transmission path along which signals of the other types are transmitted;
- iii) transmitting the signals of the other types along the first transmission path; and
- iv) transmitting the diverted signals along a second
35 transmission path.

A system illustrating an embodiment of the present invention is shown in Fig. 1. Signals of various types are transmitted to telecommunication switch 1 and therefrom over a plurality of trunks 3 to telecommunication station 5. According to this embodiment, a detector (not shown in the Fig.) detects the type of the signals received and a switch (also not shown in this Fig.) controlled by this detector, diverts these signals in accordance with a pre-defined mode of operation. An example of such pre-defined mode of operation is that as long as there is enough available bandwidth for transmission, signals of all types will be transmitted along bearer 7. However, at times when an increase in the traffic load above a certain threshold,

signals of certain type(s) e.g. facsimile signals, will not be transmitted along bearer 7. In this case, if a signal is of a voice type, it will be processed by station 5 and be forwarded along bearer 7 (the first transmission path). When the signal is of a non-fax voiceband data type signal, again, the signal may be processed by station 5 and be forwarded along bearer 7, preferably depending on the bandwidth availability. However, when a facsimile call arrives at station 5, the station's switch diverts the call to communication link 11. The voice and non-fax voiceband signals received at station 9 are decoded and transmitted over trunks 18 towards switch 19. The diverted facsimile signals are forwarded via communication link 11 and via IP Gateway 13, towards IP network 15. The diverted facsimile signals are then transmitted over an IP path defined in network 15 towards gateway 17. In gateway 17, the arriving facsimile call is directed to station 9 where it is channeled in accordance with the original assignment of trunks 18, to switch 19, and therefrom to its destination. It should also be understood that in accordance with a preferred embodiment of the present invention, the diverted facsimile signals should not necessarily be transmitted via station 9. A different path can be applied, as long as the diverted signals can be managed and controlled by the network so that they reach successfully their final destination.

Reference is now made to FIG. 2, which is a functional block diagram of a telecommunication station. The transmit side is described with respect to FIG. 2. The receive side is of a mirror symmetric description and will not be described herein. Many of the components of the telecommunication system are substantially similar to those described and claimed in the aforesaid U.S. Pat.

No. 4,171,096, which is incorporated herein by reference, and therefore, will not be described in detail. It will be appreciated that the telecommunication system described in FIG. 2 can be implemented in a point to point configuration, in a multiclique configuration, and in a multi-destination configuration, as defined in ITU-T Recommendation G.763. Additionally, it can be implemented as an access terminal for traffic compression into a packet switching network.

10 The transmission apparatus includes a trunk PCM interface (TDLI) 20 which is operative to provide interfacing between 1.544 Mbit/s or 2.048 Mbit/s PCM signals and the internal 2.048 Mbit/s (NRZ) signals employed in the telecommunication system. It is operative to provide synchronization plesiochronous buffering and optional format conversion.

Downstream of TDLI 20 there is provided a time slot interchange (TSI) 22, which provides time slot mapping. It enables up to ten 24-channel bit stream to be regrouped into eight 30/32 channel bit streams.

Digital speech interpolation circuitry (DSI) 24 provides voice compression by means of the time assignment speech interpolation (TASI) e.g. of US 4,523,309.

25 Detector 21 provides detection circuitry for classifying incoming signals as selected signals of a pre-defined type(s), such as facsimile signals, and as other signals. Other signals typically include speech, tone and non-facsimile voiceband data. In accordance with this detecting operation, switch 23 channels the signals in accordance with their type. This enables the transmission apparatus to separately compress facsimile signals and transmit them along a second transmission path and to apply the conventional compression techniques

for speech and non-facsimile voiceband data signals, and transmit them along a first transmission path.

Further compression is provided by a signal compression circuit typically comprised of a speech
5 compressing circuitry 26, e.g. Adaptive Differential Pulse Code Modulation (ADPCM) circuitry, LD-CELP circuitry, CS-ACELP circuitry and the like, and Variable Bit Rate (VBR) circuitry 28, voiceband data optimized algorithm circuitry 27 and optionally facsimile modem 29.
10 Facsimile modem 29 may be included mainly to retain the option of transmitting facsimile signals along with the other types of signals when there is enough bandwidth available.

Speech compressing circuitry 26 may employ an ADPCM
15 algorithm, in accordance with ITU-T Recommendation G.726, LD-CELP algorithm in accordance with ITU-T Recommendation G.728, CS-ACELP algorithm in accordance with ITU-T Recommendation G.729 and similar ones for compressing speech. VBR circuitry 28 is typically provided in
20 conjunction with ADPCM 26 and is operative to effectively create additional bearer channels (in excess of 62) to overcome periods of traffic overload, as described in aforesaid U.S. Pat. No. 4,747,096. The ADPCM 26 and the VBR 28, in conjunction with the DSI 24, provide a
25 compression ratio of typically 6:1 for speech signals.

Voiceband data is routed through voiceband data optimized algorithm 27 which employs ADPCM codecs optimized for reliable transmission of voiceband data, as described in aforesaid U.S. Pat. No. 4,747,096. It will
30 be appreciated that the voiceband data compression may be implemented using other algorithms, such as that of ITU-T Recommendation G. 726.

In accordance with a preferred embodiment of the present invention, facsimile signals are channeled by

switch 23 to facsimile modem 33 provided for reproducing a plurality of original facsimile binary data from a plurality of PCM signals, for optionally incorporating error correction information into the plurality of original facsimile binary data and for multiplexing the resultant signals. The optional error correction function is typically provided when the transmission network is of the type where performance is degraded. From previous explanations it should be clear that the device designated as facsimile modem 33 is not necessarily used to demodulate facsimile signals, and to be used as a means to transfer the diverted facsimile signals to the second transmission path without operating thereon.

Multiplexer 34 multiplexes the output of facsimile modem 33 into a plurality of time slots of up to 2.048 or 1.544 Mbit/s signal.

Multiplexer 31 multiplexes the out put of the signal compression stage, comprising speech compressing algorithm 26, VBR 28, voiceband data algorithm 27 and facsimile modem 29 (if applicable) into a plurality of time slots of up to 2.048 or 1.544 Mbit/s signal.

An alternative embodiment of the invention comprises a multiplexer 31 which incorporates wideband packet technology, as described in the aforementioned paper by R. W. Muise et al entitled "Experiments in Wideband Packet Technology" presented at the International Zurich Seminar on Digital Communication, April 1986. In the alternative embodiment, multiplexer 31 is operative to act as a Packet Assembler (PA) to gather and packetize a sequence of samples of compressed speech, voiceband data or facsimile data (when applicable) and to subsequently transmit the packets to a transmission network.

Interface between the 2.048 Mbit/s output of multiplexer 31 to the standard 1.544/2.048 Mbit/s

standard PCM bearer channels is provided by the Bearer PCM Interface (BDLI) 30, described in aforesaid U.S. Pat. No. 4,747,096. Similarly, a further BLDI 35 is provided to allow facsimile transmission via a different
5 transmission path.

Another embodiment of the present invention is illustrated in fig. 3. In accordance with this embodiment a telecommunication station (in this example station 110) may communicate with more than one corresponding
10 telecommunication station. In this Figure, station 110 is illustrated as having an option to communicate with both stations 120 and 130. As should be appreciated by a man skilled in the art, this embodiment may be implemented in a variety of ways. One example of such implementation, is
15 that each of the stations may communicate with any other corresponding station, each located at a different end of an IP net, where voice calls are directed to station 120 and fax calls to station 130. Another applicable example is that a station may communicate simultaneously with at
20 least two corresponding stations. Further types of digital telecommunications stations operating in tandem are also possible and it should be understood that they are all encompassed by the present invention.

Let us now turn to Fig. 3 in which two pairs of
25 telecommunication stations, namely, 100 and 200 are presented. Each one of these two pairs of stations comprises one station operating as a compressor (110 and 210, respectively) and its counter de-compressor (120 and 220 respectively). A typical operation of these stations
30 is as follows. A transmission is received at station 110 operating as a compressor. The facsimile signals are diverted to station 130 whereas the rest of the transmission is compressed and sent to station 120 operating as a de-compressor. Once identification means

of station 120 determine the existence of another operative pair of telecommunications stations (200), e.g. by detecting identification signal(s) transmitted by station 210, the mode of operation known as end-to-end
 5 compression mode is established, and the transmission will be forwarded from station 120 to station 210 in its compressed form. The transmission thus received at station 210 is further transmitted to de-compressor 220, for decompression. The facsimile signals may for example
 10 be transmitted in their demodulated form to station 210 as long as the parameters of the calls can be retrieved, e.g. keeping track after these parameters by using an outband system such as one operating in a compatible SS7 network.

15 When the transmission direction is reversed, the transmission arriving is compressed by station 220, now operating as a compressor, and sent to station 210. The latter station, identifying the existence of a further operative pair of stations (100), now downstream of the
 20 transmission path, will transmit the information received in its compressed mode. The compressed information will then be transmitted by device 110 operating now as the compressing device in the pair (100) of stations, to the now de-compressed device 110, where it will be
 25 decompressed.

A similar process, *mutatis mutandis*, may be followed when different quality of services is to be provided for the different calls reaching the telecommunication station. Such differentiation may be required depending
 30 on the type of service the transmission is directed to. For example, when video signals are received as data they may be treated differently (to have higher quality) than data signals that are transmitted in e-mail transmissions. In such a case the e-mail data signals

will be diverted from the first transmission path and the video transmission will be carried out at higher quality.

In recent years, enhanced voice compression capabilities are being used, such as by using the LD-CELP
5 and CS-ACELP compressing algorithms. However facsimile traffic, which demonstrates an increase in transmission over DCME systems, mainly during business traffic period and during lower tariff time of the day, has a negative affect upon the DCME systems. When such a system can
10 achieve 10:1 gain when voice calls are transmitted, this gain is decreased to about 6: for facsimile calls. Fig. 4 illustrates typical system gain as a function of various combinations of voice, fax and voicband data ("VBD") traffic.

15 The set of conditions chosen as a basis for the performance presented in this Figure are: bearer bandwidth - 2 Mbit/s; Fax - 90% of VBD; Fax TX% - 75% of fax transmissions; Non-fax VBD - 40 kbit/s FDX; Average Bit Per Sample (ABPS) - 1.88 for LD-CELP and 3.7 for
20 ADPCM; and freeze out $<0.1\%$. Curve a presents a system using the LD-CELP speech compressing algorithm (based on ITU-T Recommendation G.728) whereas curve b presents a system using ADPCM algorithm (based on ITU-T Recommendations G.763 and G.766). As can be seen in this
25 Figure, in case of 40% VBD calls, out of which about 90% are actually facsimile calls, the system achieves gain of 263 trunk channels compressed to 31 time slots, demonstrating an average gain of 8.48:1, where 95 trunks are used for carrying facsimile calls. When these
30 facsimile calls are diverted as suggested by the present invention to IP bearer, the average gain is increased to 9.8:1 whereas 3 additional trunks will used to carry facsimile traffic.

This type of operation allows the major part of the TDM network bandwidth to be assigned for voice transmission which is sensitive to delay, variations in delay periods as well as loss of data, while other traffic such as facsimile transmissions, less sensitive to delays, is transferred to the IP network.

Claims:

1. A digital telecommunication station operative in a telecommunication network and comprising:
 - at least one detector operative to receive at least
 - 5 two different types of signals and determine their type;
 - at least one switch controlled by one of said at least one detector, operative to channel signals received in accordance with the determination made by said one of the at least one detector;
 - 10 a first transmission means operative to transmit the received signals along a first transmission path, wherein signals of at least one type may be diverted from the first transmission path along which signals of the other types are transmitted; and
 - 15 a second transmission means operative to transmit the diverted signals of the at least one type along a second transmission path.
2. A digital telecommunication station according to
- 20 Claim 1, further comprising a storage capable of storing diverted signals of said at least one type.
3. A digital telecommunication station according to Claim 1, further comprising at least two different pairs
- 25 of compressing/decompressing devices.
4. A digital telecommunication station according to Claim 1, wherein said signals of the at least one type to be diverted are facsimile signals.
- 30 5. A digital telecommunication station according to Claim 4, further comprising a device for demodulating/re-modulating said facsimile signals.

6. A digital telecommunication station according to Claim 5, wherein said demodulating/re-modulating device comprises facsimile signal demodulator/re-modulator and forward error correction apparatus wherein the forward error correction apparatus is operative to protect the output of the facsimile demodulator.

7. A digital telecommunication station according to Claim 1, wherein said signals of the at least one type to be diverted are signals used for a service that requires a lower class of quality.

8. A digital telecommunication station according to Claim 3 and further comprising:

first identifier for determining whether the signals received are of a digital compressed form;

second identifier for determining whether the transmission path along which the signals will be transmitted includes at least one further operative means adapted for decompressing the signals when being transmitted in their compressed form;

third transmission means operative in response to a determination made by the second identifier that the transmission path does not include at least one further operative means adapted for decompressing the signals when being transmitted in their compressed form; and

fourth transmission means operative in response to a determination made by the second identifier that the transmission path does include at least one further operative means adapted for decompressing the signals being transmitted in their compressed form into the decompressed digital output signals.

9. A telecommunication system comprising:

at least one receiver at at least a second end of the transmission network; and

10. A telecommunication system comprising:

at least one receiver at at least a second end of the transmission network; and

15

12. A telecommunication system according to Claim 9,
wherein said at least one of digital telecommunication
station is capable of establishing a communication
connection with more than two digital communication
stations.

13. A method for transmission of telecommunication signals of at least two different types, the method comprising:

ii) based on step i), diverting signals of a per-defined type from a first transmission path along which signals of the other types are transmitted;

iii) transmitting the signals of the other types along the first transmission path; and

iv) transmitting the diverted signals along a second transmission path.

5

14. A method according to Claim 13, wherein the diverted signals are stored and transmitted at a later stage via said first transmission path.

10 15. A method according to Claim 14, wherein the diverted signals are stored in a storage means prior to their transmittal along a second transmission path.

ABSTRACT

A digital telecommunication station is provided, operative in a telecommunication network to receive at least two different types of signals and divert signals and divert signals of at least one of these types from the transmission path along which signals of the other types are transmitted.

[x] was/will be filed in the U.S. under 35 U.S.C. §371 by entry into the U.S. national stage of an international
(PCT) application, PCT/IL00/00355; filed on June 18, 2000, entry requested on _____*;
national stage application received U.S. Appln. No. _____*; §371/§102(e) date
_____ (* if known)

and was amended on _____ (if applicable).

(include dates of amendments under PCT Art. 19 and 34 if PCT)

I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above; and I acknowledge the duty to disclose to the Patent and Trademark Office (PTO) all information known by me to be material to patentability as defined in 37 C.F.R. §1.56.

I hereby claim foreign priority benefits under 35 U.S.C. §§ 119 (a)-(d) and 365 (b) of any prior foreign application(s) for patent, inventor's or plant breeder's rights certificate(s), or under §365(a) of any PCT application which designated at least one country other than the U.S., listed below:

Application No
130711

Country
Israel

Filing Date (MM/DD/YYYY)
6/30/1999

If I claimed foreign priority above, I hereby identify below any foreign application for patent (including an international (PCT) application designating a country other than the United States) or for an inventor's or plant breeder's certificate, having a filing date before that of the earliest application from which foreign priority is claimed (if left blank, then there are none):

Non-Priority Application No.

Country

Filing Date (MM/DD/YYYY)

I hereby claim the benefit under 35 U.S.C. §119(e) of any United States provisional applications listed below:

Application No.

Filing Date (MM/DD/YYYY)

I hereby claim the benefit under 35 U.S.C. §120 of any prior U.S. non-provisional application(s) or under §365(c) of any prior PCT international application(s) designating the U.S., listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in such U.S. or PCT international application in the manner provided by the first paragraph of 35 U.S.C. §112, I acknowledge the duty to disclose to the PTO all information which is material to patentability as defined in 37 C.F.R. §1.56 which became available between the filing date of the prior application and the national or PCT international filing date of this application:

Application No

Filing Date (MM/DD/YYYY)

Status(patented, pending,
abandoned)

As a named inventor, I hereby appoint the following registered practitioners to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith:

All of the practitioners associated with Customer Number 001444

Direct all correspondence to the address associated with Customer Number 001444, which is presently:

BROWDY AND NEIMARK, P.L.L.C.
624 Ninth Street, N.W.
Washington, D.C. 20001-5303
(202) 628-5197
